

# Service Discovery Query HTTP/TLS/JSON

## Interface Design Description

Service ID: *"query"*

### Abstract

This document describes a HTTP/TLS/JSON variant of the Service Discovery Query service.

## 1 Overview

This document describes the HTTP/TLS/JSON variant of the Service Discovery Query Eclipse Arrowhead service, which enables clients to query other Core System services. Examples of this interaction is a system that wants to check how can it call the orchestration service offered by the Orchestration core system.

This document exists as a complement to the *Service Discovery Query – Service Description* document. For further details about how this service is meant to be used, please consult that document. The rest of this document describes how to realize the Service Discovery Query service using HTTP [1], TLS [2] and JSON [3], both in terms of its functions (Section 2) and its information model (Section 3).

## 2 Service Functions

This section lists the functions that must be exposed by the Service Discovery Query service in alphabetical order. In particular, each subsection first names the HTTP method and path used to call the function, after which it names an abstract function from the Service Discovery Register SD document, as well as input and output types. All functions in this section respond with the HTTP status code 200 `Created` if called successfully. The error codes are, 400 `Bad Request` if request is malformed, 401 `Unauthorized` if improper client side certificate is provided, 500 `Internal Server Error` if Service Registry is unavailable.

### 2.1 POST `/serviceregistry/query`

Interface: `Query`  
Input: `ServiceQueryForm`

Called to query a service offered by a core system, as exemplified in Listing 1.

```
1 POST /serviceregistry/query HTTP/1.1
2
3 {
4   "interfaceRequirements": [
5     "HTTP-SECURE_JSON"
6   ],
7   "maxVersionRequirement": 1,
8   "metadataRequirements": {
9     "additionalProp1": "string",
10    "additionalProp2": "string",
11    "additionalProp3": "string"
12  },
13   "minVersionRequirement": 1,
14   "pingProviders": true,
15   "securityRequirements": [
16     "CERTIFICATE"
17   ],
18   "serviceDefinitionRequirement": "orchestration-service",
19   "versionRequirement": 1
20 }
```

Listing 1: A `Query` invocation.

## 3 Information Model

Here, all data objects that can be part of the service calls associated with this service are listed in alphabetic order. Note that each subsection, which describes one type of object, begins with the *struct* keyword, which is meant to denote a JSON Object that must contain certain fields, or names, with values conforming to explicitly named types. As a complement to the primary types defined in this section, there is also a list of secondary types in Section 3.3, which are used to represent things like hashes, identifiers and texts.

### 3.1 struct ServiceQueryForm

This structure is used to query a service from the Service Registry.

Object Field	Value Type	Description
"interfaceRequirements"	Array<Interface>	List of the required interfaces.
"maxVersionRequirement"	Version	Maximum version.
"minVersionRequirement"	Version	Minimum version.
"metadataRequirements"	Metadata	Metadata.
"pingProviders".	Boolean	Checks the availability of the providers if true
"securityRequirements"	SecureType	Type of security.
"serviceDefinitionRequirement"	Name	Service Definition.
"versionRequirement"	Version	Version of the service.

### 3.2 struct Metadata

A JSON Object which maps String key-value pairs.

### 3.3 Primitives

As all messages are encoded using the JSON format [3], the following primitive constructs, part of that standard, become available. Note that the official standard is defined in terms of parsing rules, while this list only concerns syntactic information. Furthermore, the Object and Array types are given optional generic type parameters, which are used in this document to signify when pair values or elements are expected to conform to certain types.

JSON Type	Description
Value	Any out of Object, Array, String, Number, Boolean or Null.
Object <A>	An unordered collection of [String: Value] pairs, where each Value conforms to type A.
Array <A>	An ordered collection of Value elements, where each element conforms to type A.
String	An arbitrary UTF-8 string.
Number	Any IEEE 754 binary64 floating point number [4], except for <i>+Inf</i> , <i>-Inf</i> and <i>NaN</i> .
Boolean	One out of <i>true</i> or <i>false</i> .
Null	Must be <i>null</i> .

With these primitives now available, we proceed to define all the types specified in the Service Discovery Register SD document without a direct equivalent among the JSON types. Concretely, we define the Service Discovery Register SD primitives either as *aliases* or *structs*. An *alias* is a renaming of an existing type, but with some further details about how it is intended to be used. Structs are described in the beginning of the parent section. The types are listed by name in alphabetical order.

ARROWHEAD

### **3.3.1 alias Interface = String**

A String that describes an interface in *Protocol-SecurityType-MimeType* format. *SecurityType* can be SECURE or INSECURE. *Protocol* and *MimeType* can be anything. An example of a valid interface is: "HTTPS-SECURE-JSON" or "HTTP-INSECURE-SENML".

### **3.3.2 alias Name = String**

A String that is meant to be short (less than a few tens of characters) and both human and machine-readable.

### **3.3.3 alias SecureType = String**

A String that describes an the security type. Possible values are *NOT\_SECURE* or *CERTIFICATE* or *TOKEN*.

### **3.3.4 alias Version = Number**

A Number that represents the version of the service. And example of a valid version is: 1.
